Equilibrium. The only difficulty you will encounter in doing equilibrium problems is lack of familiarity with the mechanics of doing the problems. This is overcome by doing problems. The theory is simple. If something is not moving, that is, it is in equilibrium, then the sum of the forces on it must be zero.

If an object is at equilibrium, then the forces are balanced. Balanced is the key word that is used to describe equilibrium situations. Thus, the net force is zero and the acceleration is 0 m/s/s. Objects at equilibrium must have an acceleration of 0 m/s/s. This extends from Newton's first law of motion. But having an acceleration

All examples in this chapter are planar problems. Accordingly, we use equilibrium conditions in the component form of Equation 12.7 to Equation 12.9. We introduced a problem-solving strategy in Example 12.1 to illustrate the physical meaning of the equilibrium conditions. Now we generalize this strategy in a list of steps to follow when solving static equilibrium problems for extended rigid bodies.

Equilibrium Conditions: Equilibrium in physics means, forces are in balance. The net force should be zero. In other words, forces acting downward and acting upward, and forces acting right and acting left should be equal in magnitude. Look at the example given below and try to understand what I say.

For all solutions, let T_1 be the cable on the left and T_2 be the cable on the right. The sign always has weight (W), which points down. The sign isn't going anywhere (it's not accelerating), therefore the three forces are in equilibrium. Describe this state using the language of physics — equations; in particular, component analysis equations.

For a body in equilibrium: • The resultant force on the body must be zero. and • The resultant moment of the forces on the body about all points must be zero. Sometimes it is more convenient to solve a problem just using moments. Example 14.1. A uniform beam has length 8 m and mass 60 kg. It is suspended by two ropes, as shown in the ...
