Most people use the word heat to describe something that feels warm, however in science, thermodynamic equations, in particular, heat is defined as the flow of energy between two systems by means of kinetic energy. This can take the form of transferring energy from a warm object to a cooler object. More simply put, heat energy, also called thermal energy or simply heat, is transferred from one location to another by particles bouncing into each other.

Heat transfer, any or all of several kinds of phenomena, considered as mechanisms, that convey energy and entropy from one location to another. The specific mechanisms are usually referred to as convection, thermal radiation, and conduction (see thermal conduction). Conduction involves transfer of energy and entropy between adjacent molecules, usually a slow process.

1. How Heat Affects Molecules. We explained earlier that heat energy causes molecules in an object to behave in a certain way: when an object is hot, molecules move fast. When it's cold, they move slowly. But what does that mean? In this simple heat experiment, students will better understand how molecules act in cold, hot and warm temperatures.
