Stochastic Population and Epidemic Models (Persistence and Extinction) is indeed a short, but complete, manual for the study of stochastic population and epidemic models indispensable for graduate students, for whom it was thought, but also accessible to many more audiences: professionals or simply curious on these subjects." Classic examples of population and epidemic models illustrate the probability of population or epidemic extinction obtained from the theory of branching processes. The first chapter develops the branching process theory, while in the second chapter two applications to population and epidemic processes of single-type branching process theory are explored.

The 7rst part covers stochastic models and their properties, often assuming a large community in which the disease is spread. The second part deals with statistical questions, that is, what can be said about the model and its parameters, given that an epidemic outbreak has been observed.

Stochastic epidemic models: a survey Tom Britton, Stockholm University? October 23, 2009 Abstract This paper is a survey paper on stochastic epidemic models. A simple stochas-tic epidemic model is de?ned and exact and asymptotic model properties (relying on a large community) are presented. The purpose of modelling is illustrated by

Stochastic epidemic models: a survey - arXiv

Deterministic versus stochastic epidemic models. It is important to stress that the deterministic models presented here are valid only in case of sufficiently large populations, and as such should be used cautiously. To be more precise, these models are only valid in the thermodynamic limit, where the population is effectively infinite. In stochastic models, the long-time endemic equilibrium derived above, does not hold, as there is a finite probability that the number of infected ...

3.3.1 SIS Epidemic Model In an SIS epidemic model, there is only one independent random variable, I(t), because S(t)=N-I(t), where N is the constant total population size. The stochastic process {I(t)}_{t=0} has an associated probability function, p_i(t)=Prob{I(t)=i}, for i =0,1,2,...,N and t =0,τ,2τ,..., where N i=0 p_i(t)=1. Let p₀(t)=(p₀(t),p₁(t),...,p

type models analyse epidemic processes where individuals can be in di?erent infectious states, these states representing either two competing epidemics propagating within the same population [36] or di?erent severity stages of the same infection [8]. We refer the reader to [10] for a detailed survey on stochastic epidemic models.

The 1920s saw the emergence of compartmental models. The Kermack–McKendrick epidemic model (1927) and the Reed–Frost epidemic model (1928) both describe the relationship between susceptible, infected and immune individuals in a population. The Kermack–McKendrick epidemic model was successful in predicting the behavior of outbreaks very similar to that observed in many recorded epidemics.

Mathematical modelling of infectious disease - Wikipedia

We consider a population of fixed sizeN, in which an epidemic is tak- ing place. We assume that one infectious individual initiates the epidemic and thereafter secondary (animal to animal) transmissions of the disease take place according to a stochastic SIR model.
