Structural Equation Modeling of Multivariate Time Series the process $\tau(t)$ degenerates to a simple linear time trend. The seasonal component of the structural time-series model is described by the equation $\sigma(t) + \sigma(t-1) + \dots + \sigma(t-s+1) = \omega(t)$ (14) or, equivalently,

MODELS The essence of a structural model is that it is formulated in terms of independent components which have a direct interpretation in terms of quantities of interest. One of the most important models for economic time series is the basic structural model: this consists of a trend, a seasonal and an irregular

The basic idea of structural time series models is that they are set up as regression models in which the explanatory variables are functions of time with coefficients which change over time. Thus within a regression framework a simple trend would be modeled in terms of a constant and a time with a random disturbance added on, that is

In this regard, this work provides a framework for the global (short and long term) identification of the dynamic response of a structure, of unknown properties or a given a priori numerical model, under variable operational and environmental conditions by representing the short-term dynamics via a linear-in-the parameters regressive time-series model (which may assume the form of an AutoRegressive, AutoRegressive with eXogenous input or similar model), and a Gaussian

Models include ARIMA, structural, and stochastic volatility models and their extensions. The first two classes of models explain the level and expected future level of a time series. The last class seeks to model the change over time in variability or volatility of a time series. Time series analysis is critical to prediction and forecasting.
